# Eco L3 - Globalization, Inequality, and Redistribution 

Lecture 8: The ideal tryptich of progressive taxation

Gabriel Zucman<br>gabriel.zucman@psemail.eu

## Three pillars of ideal progressive tax systems:

- Progressive comprehensive income tax
- Progressive inheritance tax
- Progressive wealth tax

## 1 Income taxation and the equity-efficiency trade-off

When the government taxes income, this has two effects

- Generates tax revenue: mechanical (positive) revenue effect
- Workers respond by reducing labor or capital supply: behavioral (negative) revenue effect

## The optimal labor income tax problem

Goal of gov. is to balance the equity gains with the efficiency losses

- Objective: A social welfare function (SWF), $W=W\left(U_{1}, \ldots, U_{n}\right)$, where $U_{i}$ is the utility of individual $i$.
- Instrument: A tax function $T(z)$ that gives the amount of taxes owed by individual with earnings $z$
- Contraints: gov. budget constraint and indiv.optimizing behavior
- The problem: Design $T($.$) to maximize SWF subject to the$ government budget constraint and individual optimization
- This problem was first solved by Mirrlees (1971). In its general form, it is difficult to solve.
- We will simplify the problem by:

1. Simplifying the tax system: piecewise linear taxes
2. Considering a special social welfare function

## Simplification number one: linear income tax

- The simplest tax system is one with a constant marginal tax rate $\tau$ and a guaranteed minimum income $G>0$ :

$$
\begin{equation*}
T(z)=\tau \cdot z-G \tag{1}
\end{equation*}
$$

- Also known as a flat tax
- The average tax rate is given by $\frac{T(z)}{z}=\tau-\frac{G}{z}$.

## Simplification number two: Rawlsian SWF

- The Rawlsian SWF is $W=\min \left(U_{1}, \ldots, U_{n}\right)$ : gov. only cares about the worst-off individual in the population
- Let's assume that the worst-off individual in the population is not able to work hence live off the transfer $G$
- A Rawlsian government then wants to maximize $G \Rightarrow$ the optimal income $\operatorname{tax} \tau$ maximizes revenue $\Rightarrow$ rech top of the Laffer curve.

## THE LAFFER CURVE

Tax revenue $R$

Laffer curve is important in two ways:

- Laffer rate is the optimum under Rawlsian social preferences
- Laffer rate represents upper bound on optimal tax rates:
- If the goal is to maximize tax revenue
- But other goals are possible

2 The optimal labor income tax rate

## Laffer rate under linear taxation

- Theorem: the Laffer rate is given by $\tau^{*}=\frac{1}{1+\varepsilon}$
- where $\varepsilon \equiv \frac{d z / z}{d(1-\tau) /(1-\tau)}$ is the the elasticity of taxable income
- With $\varepsilon \approx 0.2$ then $\tau^{*} \approx 83 \%$

## Piecewise linear tax systems

- Most tax systems are not linear, but piecewise linear: impose different marginal tax rates over different income intervals
- Within each bracket, the marginal tax rate is constant. Across brackets, marginal tax rates differ and typically increase with $Y_{L}$
- Let's focus on the Laffer rate in the highest-income tax bracket, assuming that income is Pareto-distributed at the top
- Variables pertaining to top-rate taxpayers are denoted by "hat"
- Theorem: the high-income Laffer rate is given by

$$
\hat{\tau}^{*}=\frac{1}{1+\hat{\varepsilon} \cdot a}
$$

- where $\hat{\varepsilon}$ is the elasticity of taxable income at the top
- And $a=$ Pareto coefficient
- The more unequal the distribution of income, the higher the optimal top marginal income tax rate
- The higher the elasticity of taxable income, the lower the optimal top marginal income tax rate
- Plugging real number in the formula:
- If $a \approx 2$ and $\hat{\epsilon} \approx 0.2$ then $\hat{\tau}^{*} \approx 71 \%$

## 3 Optimal capital taxation

- If inequality entirely came from labor income, it would be useless to $\operatorname{tax} \mathrm{K}$
- But in practice inheritance plays a big role
- And it is not easy to separate $L$ from $K$ income flows
$\rightarrow$ These are the two key reasons why capital should be taxed

### 3.1 Fuzzy frontier between capital and labor

Main situations where the $K / L$ frontier is fuzzy:

- Business owners can decide how much they get paid in wages vs. dividends
- Freelancers (journalists, consultants...) and self-employed (doctors, lawyers, etc.) can incorporate

Vast empirical evidence on how differential tax treatment can induce shifting:

- Finnish dual income tax system: taxes separately K income at preferred rates since $1993 \rightarrow$ people report more K income
- Carried interest in the US for hedge fund and private equity fund managers $\rightarrow$ people report capital gains instead of wages

The higher the shifting elasticity, the closer the tax rates on labor and capital income should be

- Extreme case where government cannot distinguish at all between labor and capital income
- Govt observes only $w l+r K \Rightarrow$ Only option is to have identical marginal tax rates on labor and capital
- In practice, this seems to be an important consideration when designing income tax systems, especially for top incomes

### 3.2 Optimal inheritance taxation

- Most normative theories of distributive justice put a strong emphasis on individual merit $\rightarrow$ tax bequests
- But individuals value the possibility of leaving a bequest to their children $\rightarrow$ don't tax bequests
$\rightarrow$ Interesting trade-off

## Simplified optimal inheritance tax model:

- Meritocratic Rawlsian criterion: maximize welfare of those receiving no inheritances
- Optimal inheritance tax rate:

$$
\tau_{B}=\frac{1-\bar{b}}{1+e_{B}}
$$

with $e_{B}=$ elasticity of aggregate bequests and $\bar{b}=$ relative bequest left by zero-bequest receivers

## Key insights:

- Optimal $\tau_{B}<1 /\left(1+e_{B}\right)$ revenue maximizing rate because zero-receivers care about bequests they leave
- $\tau_{B}=0$ if $\bar{b}=1$ (i.e, zero-receivers leave as much bequest as average)
- If bequests are quantitatively important, highly concentrated, and low wealth mobility then $\bar{b} \ll 1 \rightarrow$ high $\tau_{B}$

Top inheritance tax rates, 1900-2013

## 4 The proper way to tax billionaire: a wealth tax

Income flow can be difficult to observe for top wealth holders:

- Capital income retained in holding companies, trusts, etc., can create large gap between economic and taxable income
- On the contrary $W_{t i}$ is well defined

The lower the elasticity of the rate of return $\tilde{R}\left(e_{t i}\right)$ with respect to the tax rate, the higher the optimal wealth tax rate on billionaires

- Some evidence suggests $\tilde{R}\left(e_{t i}\right)$ may largely be determined by initial wealth
- Above a certain threshold, high fortunes tend to grow fast, whatever their source

Figure C4: Return on foundation wealth, 1990-2010 average Returns including realized \& unrealized gains
